

# 4xNomosWebPhoto

Dataset Creation Workflow  
By Philip Hofmann

# Use Case

4x upscaling an image that was downloaded from the web

Images from the web range from lossless good quality to downsampled and (re) compressed images for faster client web load speeds, while photography additionally could already be blurry and noisy before uploaded. This degradation workflow tries to simulate all of these cases so an upscaling model trained with it might be able to handle these use cases.

Use Case Visualization - A photo taken of me and a friend, uploaded and re-uploaded on the web (each time downscaled and compressed by the service provider). An upscale would ideally reach the original state again.

# Dataset used: Nomos-v2

For this I use the Nomos-v2 dataset as released by must on neosr and simple degrade it.

The Nomos-v2 dataset contains 6000 images of 512x512px each.

The purpose of this dataset is to distill only the best images from the academic and community datasets. A total of 14 datasets were manually reviewed, including: Adobe-MIT-5k, RAISE, LSDIR, LIU4k-v2, KONIQ, Nikon Low-Light RAW Image Dataset, DIV8k, FFHQ, Flickr2k, ModernAnimation1080, Rawsamples, SignatureEdits, Hasselblad raw samples and Unsplash.

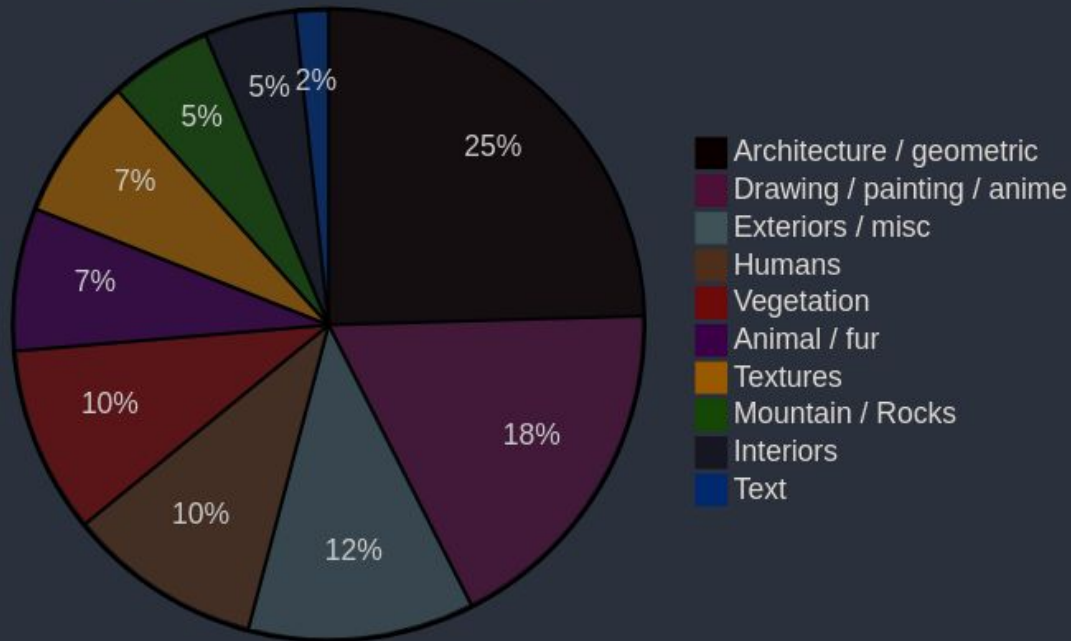

Raw images were processed on rawtherapee using prebayer deconvolution, AMaZe and CAM16 on AP1 color space.

Downsampling was done using Mitchell interpolation and post RL deconvolution.

The criteria for selection were:

- High signal-to-noise ratio (low noise)
- Diverse
- Sharp (no motion blur, shallow DOF allowed)
- Contains mixed and complex textures/shapes that cover most part of the image

Example of Nomos-v2 tiles / images (First 21 out of 6000)

# Adding Blur

I am adding lens blur with either radius 2 or 3 as visualized below

Original

Lens Radius 2 Comp 4 Ex 2

Lens Radius 3 Comp 4 Ex 2

# Adding Noise

To add noise im using my self-trained Ludvae200 degradation model as released.

The noise im using is from 1 to 5 and the temperature is from 0.06 to 1.4

Below a visualization for the min and max, it applies the noise in a spectrum, Noise 3 Temp 0.1 is just an example of a median noise it could apply in the dataset

Original

Ludvae200 - Noise 1 Temp 0.06

Ludvae200 - Noise 3 Temp 0.1

Ludvae 200 - Noise 5 Temp 0.14

# Adding Compression

Since this is images from the web, im adding jpg and webp compression again in a randomized manner, below a visualization of the max compression.

For jpg i went with quality 70 as max, which I thought should suffice, since previews in the Google search for pictures are compressed with quality 74. And for webp I chose 72 to result in the (almost) same compressed file size.

I think this should suffice for most images (we normally get better quality if training on less degradation so i am trying to keep the max reasonable) unless they went extreme on compression strength. We are also going to add re-compression to the dataset which would help with more compressed images.

Original

JPG 70

WEBP 72

Visualization of Max Compression

# Adding Re-Compression

To simulate the download and re-upload of an image from the web to a service provider, I add re-compression to the dataset with the same max strengths

# Why Variants?

We are working with different degraded lr folders here because I want to simulate the different use cases.

The benefit here is that since we are using non-degraded inputs a trained model at the end should do also well on non-degraded, meaning good quality, input. Then blur only, then noise only, blur and noise, blur and noise and compressed, blur and compressed, and so forth. Basically ensuring that it gives a good output on images still that do not have less degradations occurring, until fully degraded.

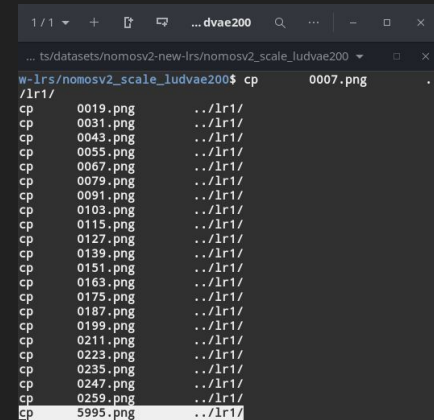

Visual example of all variants of a specific train lr image

# Created a mixed lr1 folder

Basically mixing together all the variants in the same folder, in a repetitive manner.

With batch size 12 now, each variation will appear within each batch, so this mixed lr1 folder kinda recommends that batch, at least for early stages of training.

Better would be in a randomized order. Meaning if the training software itself, one could in the config give an array of lr folders, and for each image (like '0001.png') it randomly gets it from one of the lr folders. So with longer training it would see more variance of degradation settings, also batch would matter less since randomized.

```
1 / 1 + ... dvae200 ... ts/datasets/nomosv2-new-lrs/nomosv2_scale_ludvae200 /lr1/w-lrs/nomosv2_scale_ludvae200$ cp 0007.png .. cp 0019.png ../lr1/ cp 0031.png ../lr1/ cp 0043.png ../lr1/ cp 0055.png ../lr1/ cp 0067.png ../lr1/ cp 0079.png ../lr1/ cp 0091.png ../lr1/ cp 0103.png ../lr1/ cp 0115.png ../lr1/ cp 0127.png ../lr1/ cp 0139.png ../lr1/ cp 0151.png ../lr1/ cp 0163.png ../lr1/ cp 0175.png ../lr1/ cp 0187.png ../lr1/ cp 0199.png ../lr1/ cp 0211.png ../lr1/ cp 0223.png ../lr1/ cp 0235.png ../lr1/ cp 0247.png ../lr1/ cp 0259.png ../lr1/ cp 5995.png ../lr1/
```

Mixed Ir1 folder

# Training

I trained a RealPLKSR model on this dataset (a modification by mustl on PLKSR) with neosr since im testing out that arch currently.

I did not do any fancy method but pretty barebones, I set batch to 12 to match the variants in the mixed lr1 folder, left gt\_size at 128, used a gan pretrain, and let it train for 270'000 iterations without changing the configuration during training.

I will show the configuration on the next slide, and then validation outputs. Some validation inputs are pretty strongly degraded, that is for me to more clearly see the denoising, decompression etc effects of the trained model and to draw conclusions from it.

```

The order is still important of course, first blur, then noise, then compression

Max degraded image in new dataset, original, then lens,noise,jpg,jpg

Max degraded image in old dataset, original, then lens,noise,jpg,jpg

Mixed Ir1 folder

# Training

I trained again a RealPLKSR model on this dataset with the same settings as previously.

This one is trained for less iterations, but it is enough to see the difference.

Though I got some conclusions from it again, looking at outputs (for example tree val - too many details get lost) and at the lr's, the lens blur still seems too strong.

I'll show some outputs of the new model

# New lens blur

Float implementation by umzi

Way more fine grained control for me. 0.1 steps is barely visible to me. 0.01 steps are not visibly discernible to me, but with an image diff checker i can see that there are slight differences.

I redid the blur parts of the dataset, with 0.1 as min and 1.5 as max after inspecting the lr images.

```
Open  con...  Save  ...  -  x
~/Doc...
1 | {"input": "/home/phips/Documents/datasets/
2 | 4xnomosrealweb_v3/nomosv2_scale",
3 | "output": "/home/phips/Documents/datasets/
4 | 4xnomosrealweb_v3/nomosv2_scale_lens",
5 | "process":
6 |   {
7 |     "type": "blur",
8 |     "filter": ["lens"],
9 |     "kernel": [0, 1],
10 |    "target_kernel": {
11 |      "box": [0, 2],
12 |      "gauss": [0, 2],
13 |      "median": [0, 1],
14 |      "lens": [0.1, 1.5]
15 |    },
16 |
17 |    "motion_size": [0, 10],
18 |    "motion_angle": [-30, 30],
19 |
20 |    "probability": 1
21 |  },
22 |  ],
23 |  "num_workers": 16,
24 |  "map_type": "process"
}
```

JSON Tab Width: 8 Ln 24, Col 2 INS

Original

Min Lens 0.1

Max Lens 1.5

New lens strengths

The Ir's with new lens strengths (meaning randomized manner)

LR's from the fully degraded folders, first row previous, second row new

Mixed lr1 folder, lens float rework

# Training

I then again trained a realplksr model.

The outputs looked better to the point that I was satisfied that this version would be release worthy.

So I upped gt size to 256, enabled additional losses like ldl, dists and ff, upped gt size to 512. After testing around I interpolated two of the checkpoints, and released the model as 4xNomosWebPhoto\_RealPLKSR on my models github repo.

Following outputs I prepared for the release

4xNearestNeighbor

4xNomosWebPhoto\_RealPLKSR

Example 1

Example 2

4/NearEstNeig@200

4/NomosWebPhoto\_ReaPLKSR
